

## Highly luminescent organoboron complexes (M.A. Potopnyk).

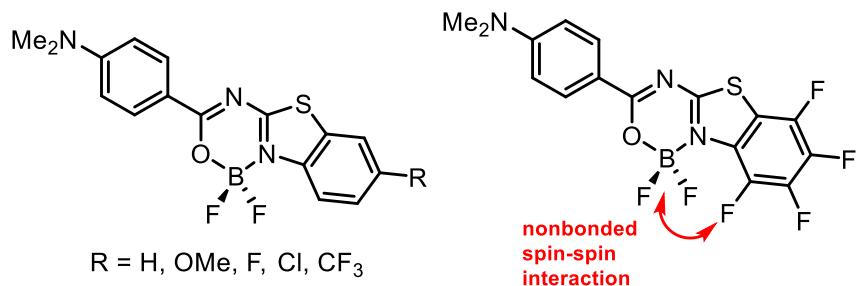

Tetracoordinated organoboron complexes, due to their photophysical properties, are among the most intensively investigated organic fluorophores. Our team has developed new *N,O*-chelated organoboron complexes based on amide ligands containing a thiazole or benzothiazole core. These compounds exhibit intensive fluorescence in solutions and solvatofluorochromism. Special attention is paid to the study of compounds exhibiting solid-state emission, in particular mechanochromic luminescent (MCL) materials. Current work is underway to discover new organoboron analogs for optoelectronic applications.
